# DERIVATION OF SIMPLE EXPRESSIONS FOR THE LIGHT INTENSITY FOR THE CASE OF DIFFRACTION BY A THIN SCREEN WITH A STRAIGHT EDGE. PART II. 

Yu.I. Terent'ev<br>Institute of Atmospheric Optics, Siberian Branch of the Academy of Sciences of the USSR, Tomsk Received August 14, 1989

#### Abstract

It is determined that the difference of the light amplitudes in the bands of the diffraction pattern due to the screen and the corresponding amplitudes of the incident wave is inverse proportional to the distance from the shadow boundary.

Simple expressions are derived for the intensity of the edge wave, and the intensity of the diffraction pattern, and are in good agreement with the experimental data.

In Part I of this paper ${ }^{1}$ it was shown that the intensity of the components of the edge wave from a screen with a straight edge is described by the equation $J_{\mathrm{e}}=A / h^{2}$

The same relationship determines the dependence of the squared difference of the light amplitudes $J_{\mathrm{r}}$ in the bands of the diffraction pattern from the screen and the corresponding amplitudes of the incident wave on $h$. It is clearly confirmed by Tables I-IV in Ref. 1 with similar $A$ values for diffraction maxima and first minima, where $h_{\text {exp }}$ is the experimental value of the distance from the bands to the shadow boundary; $J_{\mathrm{b}}$ and $J_{\mathrm{i}}$ are the light intensities in the bands of the diffraction pattern and in the incident beam without screen respectively; $\quad\left|J_{\mathrm{r}}\right|=\left(\sqrt{J_{\mathrm{b}}}-\sqrt{J_{\mathrm{i}}}\right)^{2} ; \quad$ and, $A=J_{\mathrm{p}} h_{\text {exp }}^{2}$. The above values of $h_{\text {exp }}, J_{\mathrm{b}}$, and $J_{\mathrm{i}}$ were obtained experimentally with a $30-\mu \mathrm{m}$ wide slit (Fig. 4 from Ref. 1), illuminated by a parallel light beam ( $\lambda=0.53 \mathrm{~m}$ ), selected with the help of an interference filter from the radiation of a filament lamp or $\mathrm{He}-\mathrm{Ne}$ laser, serving as the source of the cylindrical wave. The screen (a blade) was located up against the axis of the light beam, and the examined bands were located on the projection of the second half of the first maximum from the slit.

TABLE I.

| $l=6 \mathrm{~mm} ; \quad L=99.5 \mathrm{~mm} ; \quad \lambda=0.53 \mu \mathrm{~m}$ |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Band | $h_{\text {exp }}, \mathrm{mm}$ | $J_{b}$ | $J_{i}$ | $J_{r}$ | $A$ |
| $\max _{1}$ | 0.8 | 22.1 | 14.5 | 0.81 | 0.518 |
| $\min _{1}$ | 1.261 | 3 | 5.3 | 0.33 | 0.517 |
| $\max _{2}$ | 1.609 | 3.2 | 1.8 | 0.21 | 0.544 |

The decrease of $A$ with the increase of the order of the minima in these experiments is easily explained by
the decrease of the degree of overlap of the wave trains if the diffraction pattern is caused by the interference of the edge wave and the incident wave. This is facilitated by the small length of the wave trains in the light from the filament lamp, which appears to be comparable with the path difference between the edge rays and the direct rays. In the case of laser radiation (Table IV) the path difference between the interfering rays, within the limits of the examined pattern, is small in comparison with the length of the wave trains: the dependence of $A$ on the order of the minima is weakened.

TABLE II

| $l=12 \mathrm{~mm} ; \quad L=95.5 \mathrm{~mm} ; \quad \lambda=0.53 \mu \mathrm{~m}$ |  |  |  |  |  |
| :--- | :---: | ---: | ---: | :---: | :---: |
| Band | $h_{\text {exp }}, \mathrm{mm}$ | $J_{\mathrm{b}}$ | $J_{1}$ | $J_{\mathrm{r}}$ | $A$ |
| $\max _{1}$ | 0.582 | 39.7 | 28 | 1.02 | 0.345 |
| $\max _{2}$ | 1.145 | 17.3 | 13.2 | 0.28 | 0.371 |
| $\max _{3}$ | 1.540 | 7.7 | 5.7 | 0.14 | 0.340 |
| $\max _{4}$ | 1.830 | 2.9 | 1.9 | 0.11 | 0.353 |
| $\min _{1}$ | 0.9 | 13.7 | 19 | 0.43 | 0.350 |
| $\min _{2}$ | 1.350 | 6.1 | 8.2 | 0.16 | 0.282 |
| $\min _{3}$ | 1.670 | 2.3 | 3.1 | 0.06 | 0.166 |
| $\min _{4}$ | 1.970 | 0.7 | 0.9 | 0.01 | 0.049 |

While $A$ is sensitive to the order of the minima, it is independent of the order of the tabulated maxima; which in all probability indicates the possibility of a complete interference of the diffracted and incident light at the photodetector, even in the presence of a path difference between the wave trains, if the corresponding time interval is substantially less than the decay time of the stimulated oscillations of the electrons in the cathode of the photodetector.

As the measurements show, $J_{\mathrm{r}}$ is equal to the light intensity in the shadow from the screen $J_{\text {sh }}$ at the same distances from its boundary. It was impossible in these
experiments to detect the presence of the phase shift of $n$ between the light with intensity $J_{\mathrm{r}}$ and the light with intensity $J_{\text {sh }}$, which is the essential indication of an edge wave. Nevertheless, the equality of $J_{\mathrm{r}}$ and $J_{\text {sh }}$ and the fact that their dependence on $h$ obeys an edge-wave intensity distribution law allows one to conclude that the diffraction pattern from the screen and the light in the shadow region are really caused by the interference of one of its components with the direct beams and by the propagation of the other component into the shadow.

TABLE $V$.

| $\alpha, \operatorname{deg}$ | $J_{1}$ | $J_{3}$ |
| :---: | :---: | :---: |
| 0.133 | 39.4 | 40.4 |
| 0.166 | 25.5 | 26.4 |
| 0.263 | 10.4 | 10.4 |
| 0.360 | 5.5 | 5.5 |
| 0.537 | 2.6 | 2.5 |

The identification of the light in the shadow from the screen with the edge wave is also confirmed by the fact that at equal values of $l$ and for the same intensities of the incident light on the screen edge its
intensity in the shadow $J_{3}$ (Fig. 4 from Ref. 1) is equal to the intensity of the edge wave $J_{1}$ (Fig. 1 from Ref. 1) at equal deviation angles from the initial direction $\alpha$; this is confirmed by the data in Table V.

TABLE VI.

| $1, \mathrm{~mm}$ | $L, \mathrm{~m}$ | m |
| :---: | :---: | :---: |
| 6 | $J_{\max 1} / J \mathrm{c}$ |  |
| 12 | 99.5 | 1.377 |
| 24 | 99.5 | 1.374 |
| 35.5 | 99.5 | 1.374 |
| $\infty$ | 114.2 | 1.4 |
| $\varphi$ | 279.5 | 1.39 |

Furthermore, this equality demonstrates the inconsistency of Fresnel's statements ${ }^{2}$ to the effect that the energy of the edge wave is insufficient to form the diffraction pattern with the experimentally observed variations of the light intensity in the bands.

The relationship of the light in the shadow with the edge wave becomes especially clear under conditions of periodic variation of the light intensity in the plane of the screen in the direction perpendicular to its edge upon displacement of the screen in the same direction. In this case the variations of the light flux in the shadow region follow the intensity variations near the screen edge even when the distance between the maxima is $\sim 15 \mu \mathrm{~m}$.

It is well known that given a constant intensity over the width of the wave-front, the ratio of the intensity of the maximum of the diffraction pattern caused by the screen $J_{\text {max } 1}$ to $J_{1}$ does not depend on the parameters $l$ and $L$ (Fig. 4 from Ref. 1)) and is approximately equal to 1.374 according to theCornu spiral. The validity of the above-mentioned fact is confirmed, for example, by the experimental data in Table VI.

This dependence enables one to express $A$ in terms of $J_{1}$ and the parameters of the diffraction scheme. Let us do this first for the case of a cylindrical incident wave. According to relation (3) from Ref. 1 the distance from the first maximum to the shadow boundary is written in the form $h_{\max 1}=\sqrt{0.69 \lambda L \frac{L+l}{l}}$. Taking this into account, one can write the intensity of the edge wave at $h_{\max 1}$ in the form
$J_{\mathrm{e} 1}=a_{\mathrm{e} 1}^{2}=A\left|h_{\max 1}^{2}=A l\right| 0.69 \lambda L(L+l)$.
As was noted above, $J_{\mathrm{e}}=J_{\mathrm{r}}=J_{\mathrm{sh}}$, from which it follows that $\left.a_{e 1}=\left(\sqrt{J_{\text {max } 1}}-\sqrt{J_{1}}\right)=\sqrt{1.374 J_{1}}-\sqrt{J_{1}}\right)=$ $=0.1722 \sqrt{J_{1}}$ and $a_{e 1}^{2}=0.02965 J_{1}$. Substituting the value $a_{e 1}^{2}$ into Eq. (1), we find that $\mathrm{A}=\frac{0.02046 \lambda L(L+l) J_{i}}{l}$. It then follows that
$J_{e}=\frac{A}{h^{2}}=\frac{0.02046 \lambda L(L+l) J_{1}}{h^{2} l}$.
Using this formula one can easily determine the intensity of the edge wave at any $h$ provided that the $J_{1}$ values are known.

Replacing $h^{2}$ by its value given by expression (3)
in Ref. 1 allows us to write Eq. (2) in the form
$J_{e}=\frac{0.02046 J_{i}}{0.69+k}$,
which is convenient for determining $J_{\mathrm{e}}$ in the bands of the diffraction pattern.

The equation for the intensity of the edge wave enables one to derive a formula that describes the intensity of the diffraction pattern $J_{\mathrm{d}}$, assuming that the latter is due to the interference of the edge rays 2 with the directly transmitted rays 1 (Fig. 4 from Ref. 1). Based on the rule of coherent interference we have
$J_{d}=a^{2}{ }_{1}+a_{e}{ }_{e}{ }_{e}+2 a_{1} a_{e} \cos \psi=J_{1}+J_{e}+2 \sqrt{J_{1}} \sqrt{J_{e}} \cos \psi,(4)$
where $\psi$ is the phase difference between beams 1 and $2 ; \psi=2 \pi\left(\Delta_{21}-0.69 \frac{\lambda}{2}\right) / \lambda$, here $0.69 \lambda / 2$ is the path difference between the interfering beams, due to the initial phase advance of the edge wave, propagating to the illuminated side, relative to the incident wave by $0.69 \pi$ (Ref. 1); $\Delta_{21}=h^{2} l / 2 L(L+l)$. Therefore, we finally have
$\psi=\frac{\left[h^{2} l-0.69 \lambda L(L+l)\right] \pi}{\lambda L(L+l)}$.
After substituting relations (2) and (5) into expression (4) we have
$J_{d}=J_{i}\left[1+\frac{0.02046 \lambda L(L+l)}{h^{2} l}+2 \sqrt{\frac{0.02046 \lambda L(L+l)}{h^{2} l}} \times\right.$

$$
\begin{equation*}
\left.\times \cos \frac{\left[h^{2} l-0.69 \lambda L(L+l)\right] \pi}{\lambda L(L+l)}\right] . \tag{6}
\end{equation*}
$$

As can be easily seen, this equation demonstrates the simplicity of the dependence of $J_{\mathrm{d}}$ on $\lambda, L, l$, and $J_{1}$.

Simultaneously solving Eqs. (3) from Refs. 1 and 6 , we obtain an equation which characterizes the light intensity in the maxima and minima of the diffraction pattern:

$$
\begin{equation*}
J_{b}=\left[1 \pm \sqrt{\frac{0.02046}{0.69+k}}\right)^{2} J_{1} . \tag{7}
\end{equation*}
$$

Note that $k=0,2,4 \ldots$ correspond to the maxima, and $k=1,3,5 \ldots$ correspond to the minima, of the pattern. In the case of $J_{\mathrm{i}}(h)$, for example, if the bands are localized on the second half of the first maximum from the slit S, illuminated by the parallel beam, we have

$$
\begin{align*}
& J_{d}=J_{i}(h)+\frac{0.02046 \lambda L) L+l) J_{1 e}}{h^{2} l}+2 \sqrt{J_{1}(h)} \times \\
& \times \sqrt{\frac{0.02046 \lambda L(L+l) J_{i e}}{h^{2} l} \cos \frac{\left[h^{2} l-0.69 \lambda L(L+l)\right] \pi}{\lambda L(L+l)} ;}  \tag{8}\\
& J_{\mathrm{b}}=\left[\sqrt{J_{1}(h)} \pm \sqrt{\frac{0.02046 \lambda L) J_{i e}}{0.69+k}}\right]^{2} \tag{9}
\end{align*}
$$

where $J_{\mathrm{ie}}$ is the intensity of the incident beam in at the edge of the shadow without a screen.

The correctness of Eq. (8) is confirmed by Table VII, which contains results of a comparison of the calculated light intensity $J_{\mathrm{dr}}$ in the range between the first maximum and the minimum of the diffraction pattern with its experimental values $J_{\text {dexp }}$, obtained for $l=12 \mathrm{~mm}$, where $L=99.5 \mathrm{~mm}$; $J_{\text {ie }}=36$ rel.units, where $\Delta J_{\text {expc }}=J_{\text {dexp }}-J_{\text {dc }}$.

TABLE VII.

| Band | $h_{\text {exp }}, \mathrm{mm}$ | $J_{1}$ | $J_{\text {dexp }}$ | $\Psi$ | $\cos \Psi$ | $J_{e}$ | $J_{d c}$ | $\Delta J_{\text {exp }}$ |
| :---: | :---: | :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| $\max _{1}$ | 0.582 | 27.5 | 39.2 | $14^{\prime}$ | 1 | 1.07 | 39.4 | -0.2 |
|  | 0.601 | 27 | 38.6 | $8^{\circ} 29^{\prime}$ | 0.989 | 0.99 | 38.3 | 0.3 |
|  | 0.676 | 25.2 | 32.3 | $43^{\circ} 40^{\prime}$ | 0.723 | 0.79 | 32.4 | -0.1 |
|  | 0.751 | 23 | 24.4 | $82^{\circ} 59^{\prime}$ | 0.122 | 0.64 | 24.6 | -0.2 |
|  | 0.722 | 22.5 | 22.5 | $94^{\circ} 44^{\prime}$ | -0.083 | 0.61 | 22.5 | 0 |
|  | 0.826 | 21.2 | 17.6 | $126^{\circ} 26^{\prime}$ | -0.594 | 0.53 | 17.8 | -0.2 |
| $\min _{1}$ | 0.901 | 19 | 13.7 | $174^{\circ} 1^{\prime}$ | -0.995 | 0.45 | 13.7 | 0 |
|  | 0.910 | 18.8 | 13.6 | $180^{\circ}$ | -1 | 0.44 | 13.5 | 0.1 |

Note that in order to obtain equality between $J_{\mathrm{dc}}$ and $J_{\text {dexp }}$ it is necessary to carefully determine the location of the shadow boundary.

The validity of Eqs. (7) and (9) is confirmed by the experimental data shown in Tables VIII and IX ( $l=12 \mu \mathrm{~m}, L=99.5 \mu \mathrm{~m}, I_{\mathrm{ie}}=36$ rel. units).

TABLE VIII.

| $\min _{3}$ | 1.670 | 3.1 | 2.3 | 1.96 | 0.34 |

In the case of a parallel incident beam $l=\infty$, and Eqs. (2), (6), and (8) simplify to
$J_{e}=\frac{0.02046 \lambda L J_{i}}{h^{2}} ;$
$J_{d}=\left[1+\frac{0.02046 \lambda L}{h^{2}}+2 \sqrt{\frac{0.02046 \lambda L}{h^{2}}} \cos \frac{\left(h^{2}-0.69 \lambda L\right) \pi}{\lambda L}\right] J_{I^{\prime}}$
(11)
and
$J_{d}=J_{i}(h)+\frac{0.02046 \lambda L J_{i e}}{h^{2}}+2 \sqrt{J_{i}(h) \frac{0.02046 \lambda L J_{i e}}{h^{2}}} \times$
$\times \cos \frac{\left(h^{2}-0.69 \lambda L\right) \pi}{\lambda L}$.
Relations (3), (7), and (9) remain unchanged. The validity of Eq. (9) in the case of a parallel incident beam, obtained using a collimating objective after the slit, is shown in Tables X and XI.

TABLE $X$.

| $L=114.2 \mathrm{~mm} ;$ |  |  |  |  |  |
| :--- | :--- | :---: | :---: | :---: | :---: |
| $J_{\text {ie }}=33.5$ |  |  |  |  |  |
| Band | $h_{\text {exp }}, \mathrm{mm}$ | $J_{i}$ | $J_{\text {dexp }}$ | $J_{\text {dr }}$ | $\Delta J_{\text {expc }}$ |
| $\max _{1}$ | 0.204 | 27.2 | 38.25 | 38.59 | -0.34 |
| $\max _{2}$ | 0.4 | 17.9 | 22.05 | 22.43 | -0.38 |
| $\max _{3}$ | 0.526 | 10 | 12.35 | 12.56 | -0.21 |
| $\max _{4}$ | 0.632 | 5.65 | 7 | 7.27 | -0.27 |

The above results demonstrate quite definitely that the diffraction pattern from the screen is really formed by the interference of the edge and incident waves. At the same time, the location of bands and the values of $J_{\mathrm{d}}$ obtained in accordance with

TABLE XI.

| $L=279.5 \mathrm{~mm} ;$ |  |  |  |  |  |

| $\min _{1}$ | 0.520 | 23 | 15.9 | 15.5 | 0.4 |
| $\min _{2}$ | 0.766 | 7 | 4.6 | 4.26 | 0.34 |

Fresnel's ideas for $J_{\mathrm{i}}=$ const are confirmed experimentally.

To better understand the reason for this, consider Fig. 1, where the distribution of the light intensity in the shadow from the screen is shown,
where curve 1 characterizes the distribution $J_{\text {sh }}$ based on the Cornu spiral ${ }^{3}$; 2 is the experimental curve, and curve 3 corresponds to the dependence $\mathrm{J}_{\mathrm{sh}}=A / h^{2}$. In the corresponding experiments $l=35.5 \mu \mathrm{~m}$, $L=99.5 \mu \mathrm{~m}$, and $h_{\max 1}=0.372 \mu \mathrm{~m}$. As can be seen from the figure, at distances $h_{\delta} \geq 0.4 \mu \mathrm{~m}$ all three curves coincide. Therefore, for $h \geq h_{\delta}$ the distribution $J_{\mathrm{sh}}$, based on the Cornu spiral, is equivalent to the intensity distribution in the edge wave.

At distances $h \leq h_{\mathrm{C}}$ Eq. (2) loses meaning. Since under such conditions $h_{\mathrm{C}}<h_{\max }$, relations (6)-(9) are valid for all of the bands of the diffraction pattern.

The deviation angle of the diffracted beams (from the initial direction) corresponding to the critical distance $h_{\mathrm{C}}$ is $\varepsilon_{\mathrm{C}}=h_{\mathrm{C}} / L=0.162^{\circ}$.

If $\varepsilon_{\mathrm{C}}$ is independent of $L$, then $h_{\mathrm{C}} \sim L$. According to Eq. (3) from Ref. 1 for $l \ll L h_{\mathrm{b}}$ is also proportional to $L$. Therefore, in the case of diverging incident beams, the diffraction bands should not pass into the anomalous region as $L$ increases.

If the incident beam is parallel, $h_{\mathrm{b}}$ increases more slowly than $h_{\mathrm{C}}$ as $L$ increases because $h_{\mathrm{b}} \sim \sqrt{L}$. As a result, at large $L$ the bands can be found in the region where the band contrast range decreases. For example, the calculation made in accordance with the experimental dependence $J_{\text {sh }}=f(h)$ for $L=279.5 \mathrm{~mm}$ shows that at $L=300 \mathrm{~m}$ $J_{\max 1} / J_{1}=1.033$ and not 1.374.

FIG. 1. Distribution of the light intensity in the shadow from the screen in the case of a cylindrical incident wave.

For a parallel incident beam, $\varepsilon_{\mathrm{C}}$ has smaller values, and the behavior of curves 1,2 , and 3 is analogous to that for a diverging beam. This is confirmed by Fig. 2a ( $L=114 \mu \mathrm{~m}, \quad h_{\max 1}=0.204 \mathrm{~mm}, \quad h_{\mathrm{c}}=0.144 \mathrm{~mm}$, $\left.\varepsilon_{\mathrm{c}}=0.072^{\circ}, \quad h_{\delta}=0.163 \mathrm{~mm}\right)$ and by Fig. 2b $\left(L=279.5 \mathrm{~mm}, \quad h_{\max 1}=0.32 \mathrm{~mm}, \quad \varepsilon_{\mathrm{c}}=0.053^{\circ}\right.$, $h_{\delta}=0.345 \mathrm{~mm}$ ). According to the Cornu spiral, the amplitude difference of the bands in the diffraction pattern and the incident light without a screen, as in the case of interference between the edge wave and the
incident wave, is equal to the amplitude of the light in the shadow at the same values of $h$, that is, $\sqrt{J_{S H}}=\sqrt{J_{b}}-\sqrt{J_{1}}$. This is the second cause of the equality between the intensities of the diffraction bands according to Fresnel and their values based on Young's idea. However, Fresnel's notions are valid only for $J_{1}=$ const and for a larger width of the incident beam in the plane of the screen. When $J_{1}$ is not constant, for example, it decreases with approach to the edge of the beam (across its width) and is constant on the shadow boundary, then the form and dimensions of the Cornu spiral are changed. Consequently, $J_{\text {SH }}$ and $\left(\left(\sqrt{J_{b}}-\sqrt{J_{1}}\right)^{2}=J_{S H}\right.$ also differ.
If the light in the shadow and in the bands is due to the edge wave, then the indicated quantities remain their former values, as confirmed by experiment.

FIG. 2. Distribution of the light intensity in the shadow from the screen for an incident plane wave for $L=114.2 \mathrm{~mm}(a)$ and $L=279.9 \mathrm{~mm}(b)$.

TABLE XII.

| $\max _{4}$ | 9.8 | 8.1 | 1.21 | 0.08 | 0.282 | 5.391 | 29. 1 | 1.113 | 1. 126 | 0.99 |

We shall demonstrate this result using data from Table XII, where $J_{\mathrm{b}}$ is the intensity of the bands in the experiment with $J_{\mathrm{i}}(h)$ at $l=24 \mathrm{~mm}, L=99.5 \mathrm{~mm}$, $\lambda=0.53 \mathrm{~mm}, \quad a_{\mathrm{r}}=\sqrt{J_{r}} \quad, \quad J_{\mathrm{r}}=\left(\sqrt{J_{b}}-\sqrt{J_{i}}\right)^{2}$, $a_{1 \mathrm{e}}=\sqrt{J_{i e}}, J_{\mathrm{C}}$ is the band intensity according to the Cornu spiral. Using the values of $a_{\mathrm{r}}$, one can calculate the intensity $J_{\mathrm{b}}^{\prime}$ of the bands at constant $J_{\mathrm{i}}=J_{\text {ie }}$ from the formula $J_{\mathrm{b}}^{\prime}=\left(a_{\mathrm{ie}} \pm a_{\mathrm{r}}\right)^{2}$. As can be seen from the ratio $J_{\mathrm{b}}^{\prime} / J_{\mathrm{C}}$, the obtained values are practically equal to $J_{\mathrm{C}}$. So, $J_{\mathrm{r}}=J_{\mathrm{SH}}$ does not depend on the distribution of $J_{\mathrm{i}}$ across the wave front.

The inadequacy of Fresnel's ideas follows also from the lower values of $J_{\mathrm{d}}$ at the shadow the boundary compared with the experimental values (see Figs. 1-3).
